

## CLAIMS

[1] A method of photographing an inspected portion of a subject, comprising the steps of:

- 5           arranging a camera that has an automatic focusing function in such a way that it can swivel to a prescribed position facing the subject to be inspected;  
              swiveling the camera in such a way that its field of view moves sequentially along an inspected portion of the subject;  
              capturing an image, by means of the camera, every time the camera's field of  
10       view reaches an inspected portion of the subject; and  
              inspecting the condition of the subject by processing the image data of the inspected portion that was photographed.

[2] The method of photographing according to claim 1, wherein

- 15           the camera has an automatic exposure adjustment function that automatically adjusts the exposure when an inspected portion of the subject is photographed in color.

[3] The method of photographing according to claim 1, wherein

- 20           the camera has a focal distance change function that adjusts the focal distance of the camera in such a way that every time the camera's field of view reaches an inspected portion of the subject, the resolution of the photographed range is substantially constant.

[4] A method of inspecting the state of adhesion of a paste-type member, comprising the steps of:

- arranging a camera that has an automatic focusing function in such a way that it can swivel to a prescribed position facing the subject, to the upper surface of an outer edge of which a paste-type member adheres in the form of a continuous strip;  
30           swiveling the camera in such a way that its field of view moves sequentially along an outer edge of the subject;  
              capturing an image, by means of the camera, every time the camera's field of view reaches an inspected portion of the paste-type member that adheres in the form of a strip to the upper surface of an outer edge of the subject;

extracting color or shading from the captured image and deleting noise from the image data of the captured image;

sequentially detecting the width of the extracted strip-shaped region of the paste-type member;

5       judging whether or not the strip-shaped region is of a prescribed width; and

determining if the state of adhesion of the paste-type member is defective by judging whether the width of the detected strip-shaped region is too much wider or too much narrower than the prescribed width.

10       [5] The method of inspecting the state of adhesion of a paste-type member according to claim 4, further comprising the step of:

displaying on a display device the judgment result of whether the width of the detected strip-shaped region is too much wider or too much narrower than the prescribed width.

15

[6] The method of inspecting the state of application of a paste-type member according to claim 4, wherein

the paste-type member that adheres to the upper surface of an outer edge of the subject in the form of a continuous strip is a liquid gasket.

20

[7] A photographic device for inspecting the condition of a member that adheres to an inspected portion of a subject, comprising:

a camera that has an automatic focusing function and is arranged in such a way that it can swivel to a prescribed position facing the subject to be inspected;

25       driving means for driving the camera in such a way that the camera's field of view moves sequentially along an inspected portion of the subject;

means for operating the camera in such a way that every time its field of view reaches an inspected portion of the subject, the camera photographs the inspected portion; and

30       image processing means for processing the image data of an inspected portion that was photographed by the camera.

[8] The photographic device according to claim 7, wherein

the camera has a focal distance change function that adjusts the focal distance of the camera in such a way that every time the camera's field of view reaches an inspected portion of the subject, the resolution of the photographed range is substantially constant.

5

[9] A device for inspecting the state of adhesion of a paste, comprising:

a camera that has an automatic focusing function and is arranged in such a way that it can swivel to a prescribed position facing a subject, to the upper surface of an outer edge of which a paste is applied in the form of a continuous strip;

10

driving means for driving the camera in such a way that the camera's field of view moves sequentially along an outer edge of the subject;

means for operating the camera in such a way that every time its field of view reaches an inspected portion of the paste that adheres in a strip shape to the upper surface of an outer edge of the subject, the camera photographs the paste that is

15

located at the inspected portion;

processing means for extracting color or shading from the image captured by the camera and delete noise from the image data of the image; and

judgment means for sequentially detecting the width of the extracted strip-shaped region of the paste, judging whether or not the strip-shaped region is of a prescribed width, and determining if the state of adhesion of the paste is defective by judging whether the width of the detected strip-shaped region is too much wider or too much narrower than the prescribed width.

20

[10] The device for inspecting the state of adhesion of a paste according to claim 9, characterized by further comprising:

25

a display device that displays the judgment result in a visually recognizable way when the state of adhesion of the paste is judged to be defective by the judgment means.
